PHASE 8 / SAME-CONTEXT FULL VS APPEND / 16K HISTORY

How much delay remains after injection?

Single RTX 4090 | Qwen2.5-7B | Independent 128-token decode histories | 16K history + 1K new input | 5 repeats

Signed differences are summed from step 0: slower steps add delay and faster steps subtract it. Shading = SD of trial cumulative sums, n=5.

Curves end at the last common full-batch, matched step across both scenarios and all five repeats. Partial-batch tails remain in the derived audit CSV.

A plateau indicates little net additional delay; it does not prove every subsequent step is unaffected. Later spikes and host/observer stalls are retained.
